Help Desk Ticket Analysis: Key Findings

1. Many tickets have no known priority

Of the 43,352 tickets reviewed, 25,989—about 60%—are marked “Unknown” for priority. This makes it harder to understand how urgent the tickets were and compare work across priority levels.

Recommendation: Check why so many tickets have an unknown priority. Consider requiring a priority when new tickets are created, where that makes sense for the help desk.

2. Resolution times vary widely

For the 43,048 tickets with resolution dates, the average time to resolve was 864.04 days, while the median was 45.46 days. The large difference suggests that a smaller number of tickets had very long calendar resolution times. Calendar time does not show how much active work was spent on a ticket.

Recommendation: Review the longest-running tickets and check whether their dates represent real resolution times. The data alone does not explain why they took so long.

3. Known priority levels are associated with different resolution times

Among tickets with a known priority, the median resolution time ranged from 3.75 days for Highest priority to 9.05 days for Low priority. This shows an association between assigned priority and resolution time; it does not prove that priority caused the difference or that the process was effective.

Recommendation: Review this pattern alongside workload, ticket type, and service targets before making decisions about team performance.

4. Unknown-priority tickets need further investigation

Unknown-priority tickets had a median resolution time of 1,400.40 days, far longer than tickets with known priorities. This may reflect older records, data migration, missing priority information, or other differences. The analysis does not establish the cause.

Recommendation: Compare ticket creation and resolution dates, priority-field history, closure patterns, and ticket types. This can help determine whether the long durations reflect actual service delays or historical/data-recording issues.

Overall conclusion

The data shows a substantial gap in priority information and a highly uneven spread of resolution times. More investigation is needed before treating long durations as evidence of current service delays or using the results to judge operational performance.
